

2017-18 Seasonal Influenza Vaccine Dosage for Children

Flu vaccine dosage is based on the person's **age and the flu vaccine product** that is used.¹ A study in 2016 found that flu vaccine was most frequently involved in reported vaccine errors (20%) and was the most common type of vaccine implicated in age-related vaccine errors.² It is important to prevent flu vaccine administration errors to ensure children are adequately protected against influenza.

For children aged **6-35 months**, the dosage is dependent on the flu vaccine product that is administered. There are currently 2 licensed flu vaccine products for children aged 6-35 months: Fluzone® and FluLaval®.

If You're Using This Vaccine... ¹	Dosage for Ages 6-35 Months	If 2 Doses are Needed... ³
Fluzone® (Sanofi Pasteur)	0.25 mL	Give 0.25 mL today, 4 weeks later give 0.25 mL
FluLaval® (GSK)	0.5 mL	Give 0.5 mL today, 4 weeks later give 0.5 mL

Refer to the Flu Vaccine Presentation Chart (see footnote 1) for available presentations of each of these vaccines.

For all persons aged **3 years and older**, seasonal flu vaccine dosage is **0.5 mL regardless of the flu vaccine product** being administered.

If 2 doses of 2017-18 flu vaccine are needed, the same vaccine product **does not** need to be used for both doses. Use any age-appropriate flu vaccine that is available that day, ensuring you use the correct dosage. Dosage is based on the child's age on the day of vaccine administration. For example:

- If a child is aged **2 years and 11 months** for dose 1, use the above table to determine the dosage based on **flu vaccine product used**.
- When the child returns 4 weeks later for dose 2 and is **now aged 3 years**, the dosage is **0.5 mL** regardless of flu vaccine product used.

Examples of how to correct pediatric flu vaccine dosage administration errors^{4, 5}:

1.) A 6-month-old was inadvertently given a 0.25 mL dose of FluLaval® rather than the recommended 0.5 mL dose. What should I do?

If the error is recognized while the child is still in the office, you can give a second 0.25 mL dose of FluLaval® to correct this vaccine error. If the error is not discovered until later, you should revaccinate with a full dose (either 0.25 mL of Fluzone® or 0.5 mL of FluLaval®) as soon as possible. Revaccinating the day after the initial substandard dose was administered is safe and recommended if feasible.

2.) A 2-year-old was inadvertently given 0.5 mL from a Fluzone® multi-dose vial rather than the recommended 0.25 mL dose. What should I do?

This is more than an age-appropriate dose. The dose should be counted as valid. Notify the parent/guardian about the error. Ensure that office staff receive education to prevent vaccine administration errors. If a second dose is needed for this child, administer an age-appropriate dose (use the table above) 4 weeks later.

3.) A 5-year-old was inadvertently given a 0.25 mL dose of Fluzone® rather than the recommended 0.5 mL dose. What should I do?

If the error is recognized while the child is still in the office, you can give a second 0.25 mL dose of Fluzone® to correct this vaccine error. If the error is not discovered until later, you should revaccinate the 5-year-old with a 0.5 mL dose of Fluzone®, a 0.5 mL dose of FluLaval®, or another age-appropriate flu vaccine as soon as possible. Revaccinating the day after the initial substandard dose was administered is safe and recommended if feasible.
